OFFICIAL REPOSITORY

Last pushed: 9 days ago

Repo Info (/ /php/)

Short Description

While designed for web development, the PHP scripting language also provides generalpurpose use.

Full Description

Note: the description for this image is longer than the Hub length limit of 25000, so has been trimmed. The full description can be found at https://github.com/docker-library/docs/tree/master/php/README.md (https://github.com/docker-library/docs/tree/master/php/README.md). See docker/hub-beta-feedback#238 (https://github.com/docker/hub-beta-feedback/issues/238) for more information.

the latest release (https://github.com/docker/docker-ce/releases/latest) (down to 1.6 on a best-effort basis)

What is PHP?

PHP is a server-side scripting language designed for web development, but which can also be used as a general-purpose programming language. PHP can be added to straight HTML or it can be used with a variety of templating engines and web frameworks. PHP code is usually processed by an interpreter, which is either implemented as a native module on the web-server or as a common gateway interface (CGI).

wikipedia.org/wiki/PHP (http://en.wikipedia.org/wiki/PHP)

How to use this image

Create a Dockerfile in your PHP project

```
FROM php:7.2-cli
COPY . /usr/src/myapp
WORKDIR /usr/src/myapp
CMD [ "php", "./your-script.php" ]
```

Then, run the commands to build and run the Docker image:

```
$ docker build -t my-php-app .
$ docker run -it --rm --name my-running-app my-php-app
```

Run a single PHP script

For many simple, single file projects, you may find it inconvenient to write a complete Dockerfile. In such cases, you can run a PHP script by using the PHP Docker image directly:

```
$ docker run -it --rm --name my-running-script -v "$PWD":/usr/src/n
```

How to install more PHP extensions

Many extensions are already compiled into the image, so it's worth checking the output of php -m or php -i before going through the effort of compiling more.

We provide the helper scripts docker-php-ext-configure, docker-php-ext-install, and docker-php-ext-enable to more easily install PHP extensions.

In order to keep the images smaller, PHP's source is kept in a compressed tar file. To facilitate linking of PHP's source with any extension, we also provide the helper script docker-php-source to easily extract the tar or delete the extracted source. Note: if you do use docker-php-source to extract the source, be sure to delete it in the same layer of the docker image.

```
FROM php:7.2-cli
RUN docker-php-source extract \
# do important things \
&& docker-php-source delete
```

PHP Core Extensions

For example, if you want to have a PHP-FPM image with iconv and gd extensions, you can inherit the base image that you like, and write your own Dockerfile like this:

Remember, you must install dependencies for your extensions manually. If an extension needs custom configure arguments, you can use the docker-php-ext-configure script like this example. There is no need to run docker-php-source manually in this case, since that is handled by the configure and install scripts.

See <u>"Dockerizing Compiled Software"</u> (https://tianon.xyz/post/2017/12/26/dockerize-compiled-software.html) for a description of the technique Tianon uses for determining the necessary build-time dependencies for any bit of software (which applies directly to compiling PHP extensions).

PECL extensions

Some extensions are not provided with the PHP source, but are instead available through PECL (https://pecl.php.net/). To install a PECL extension, use pecl install to download and compile it, then use docker-php-ext-enable to enable it:

```
FROM php:7.2-cli
RUN pecl install redis-4.0.1 \
    && pecl install xdebug-2.6.0 \
    && docker-php-ext-enable redis xdebug

FROM php:5.6-cli
RUN apt-get update && apt-get install -y libmemcached-dev zlib1g-de && pecl install memcached-2.2.0 \
    && docker-php-ext-enable memcached
```

It is *strongly* recommended that users use an explicit version number in their <code>peclinstall</code> invocations to ensure proper PHP version compatibility (PECL does not check the PHP version compatibility when choosing a version of the extension to install, but does when trying to install it).

For example, memcached-2.2.0 has no PHP version constraints (https://pecl.php.net/package/memcached/2.2.0)
(https://pecl.php.net/package/memcached/2.2.0), but memcached-3.0.4 requires PHP 7.0.0 or newer (https://pecl.php.net/package/memcached/3.0.4)
(https://pecl.php.net/package/memcached/3.0.4)). When doing pecl install memcached (no specific version) on PHP 5.6, PECL will try to install the latest release and fail.

Beyond the compatibility issue, it's also a good practice to ensure you know when your dependencies receive updates and can control those updates directly.

Unlike PHP core extensions, PECL extensions should be installed in series to fail properly if something went wrong. Otherwise errors are just skipped by PECL. For example, pecl install memcached-2.2.0 && pecl install redis-2.2.8 instead of pecl install memcached-2.2.0 redis-2.2.8. However, docker-php-ext-enable memcached redis is fine to be all in one command.

Other extensions

Some extensions are not provided via either Core or PECL; these can be installed too, although the process is less automated:

```
FROM php:5.6-cli
RUN curl -fsSL 'https://xcache.lighttpd.net/pub/Releases/3.2.0/xcac
&& mkdir -p xcache \
    && tar -xf xcache.tar.gz -C xcache --strip-components=1 \
    && rm xcache.tar.gz \
    && ( \
        cd xcache \
        && phpize \
        && ./configure --enable-xcache \
        && make -j "$(nproc)" \
        && make install \
    ) \
    && rm -r xcache \
    && docker-php-ext-enable xcache
```

The docker-php-ext-* scripts *can* accept an arbitrary path, but it must be absolute (to disambiguate from built-in extension names), so the above example could also be written as the following:

```
FROM php:5.6-cli
RUN curl -fsSL 'https://xcache.lighttpd.net/pub/Releases/3.2.0/xcac
&& mkdir -p /tmp/xcache \
&& tar -xf xcache.tar.gz -C /tmp/xcache --strip-components=1 \
&& rm xcache.tar.gz \
&& docker-php-ext-configure /tmp/xcache --enable-xcache \
&& docker-php-ext-install /tmp/xcache \
&& rm -r /tmp/xcache
```

Running as an arbitrary user

For running the Apache variants as an arbitrary user, there are several choices:

- If your kernel <u>is version 4.11 or newer</u>
 (https://github.com/moby/moby/issues/8460#issuecomment-312459310), you can add --sysctl net.ipv4.ip_unprivileged_port_start=0 and then --user should work as it does for FPM.
- If you adjust the Apache configuration to use an "unprivileged" port (greater than 1024 by default), then --user should work as it does for FPM regardless of kernel version.
- Otherwise, setting APACHE_RUN_USER and/or APACHE_RUN_GROUP should have the desired effect (for example, -e APACHE_RUN_USER=daemon or -e APACHE_RUN_USER=#1000 -- see the Apache_User_directive documentation for details on the expected syntax (https://httpd.apache.org/docs/2.4/mod/mod_unixd.html#user)).

For running the FPM variants as an arbitrary user, the --user flag to docker run should be used (which can accept both a username/group in the container's /etc/passwd file like --user daemon or a specific UID/GID like --user 1000:1000).

"E: Package 'php-XXX' has no installation candidate"

As of <u>docker-library/php#542</u> (https://github.com/docker-library/php/pull/542), this image blocks the installation of Debian's PHP packages. There is some additional discussion of this change in <u>docker-library/php#551</u> (comment) (https://github.com/docker-library/php/issues/551#issuecomment-354849074), but the gist is that installing Debian's PHP packages in this image leads to two conflicting installations of PHP in a single image, which is almost certainly not the intended outcome.

For those broken by this change and looking for a workaround to apply in the meantime while a proper fix is developed, adding the following simple line to your <code>Dockerfile</code> should remove the block (with the strong caveat that this will allow the installation of a second installation of PHP, which is definitely not what you're looking for unless you really know what you're doing):

RUN rm /etc/apt/preferences.d/no-debian-php

The *proper* solution to this error is to either use FROM debian: XXX and install Debian's PHP packages directly, or to use docker-php-ext-install, pecl, and/or phpize to install the necessary additional extensions and utilities.

Configuration

This image ships with the default https://github.com/php.ini-development and php.ini-production configuration files.

It is *strongly* recommended to use the production config for images used in production environments!

The default config can be customized by copying configuration files into the \$PHP_INI_DIR/conf.d/ directory.

Example

Use the default production configuration
RUN mv "\$PHP_INI_DIR/php.ini-production" "\$PHP_INI_DIR/php.ini"

Override with custom opcache settings
COPY config/opcache.ini \$PHP_INI_DIR/conf.d/

Image Variants

FROM php:7.2-fpm-alpine

The php images come in many flavors, each designed for a specific use case.

Some of these tags may have names like jessie or stretch in them. These are the suite code names for releases of <u>Debian (https://wiki.debian.org/DebianReleases)</u> and indicate which release the image is based on.

php:<version>-cli

This variant contains the PHP CLI

(https://secure.php.net/manual/en/features.commandline.php) tool with default mods. If you need a web server, this is probably not the image you are looking for. It is designed to be used both as a throw away container (mount your source code and start the container to start your app), as well as a base from which to build other images.

It also is the only variant which contains the (not recommended) php-cgi binary, which is likely necessary for some things like PPM (https://github.com/php-pm/php-pm).

Note that all variants of php contain the PHP CLI (/usr/local/bin/php).

php:<version>-apache

This image contains Debian's Apache httpd in conjunction with PHP (as mod_php) and uses mpm_prefork by default.

Apache with a Dockerfile

FROM php:7.2-apache
COPY src/ /var/www/html/

Where src/ is the directory containing all your PHP code. Then, run the commands to build and run the Docker image:

console

\$

Docker Pull Command

docker pull php
